FraudLens: A Behaviour Based Risk Scoring Framework for Financial Fraud Detection

Major Project submitted to
Amity School of Engineering and Technology
Amity University Jharkhand

in partial fulfilment of the requirements for
the degree of
Bachelor of Technology

from
Department of Computer Science and Engineering

by
Aanya Sinha

under the guidance of
Dr. Vandana Singh

Amity School of Engineering and Technology
AMITY UNIVERSITY
Ranchi-834002, Jharkhand, India

Certificate

This is to certify that the project work entitled "FraudLens: A Behaviour Based Risk Scoring Framework for Financial Fraud Detection" has been prepared by "Aanya Sinha"under my supervision and guidance. The thesis is his original work completed after careful research and investigation. The work of the thesis is of the standard expected of a candidate for the Bachelor of TechnologyProgramme in Artificial Intelligence and I recommend that it be sent for evaluation.

Name and Signature of the Head of Institution

Declaration

I, Aanya Sinha, registered as undergraduate scholar, bearing "Registration Number" for the Bachelor of TechnologyProgramme under the Amity School of Engineering and Technologyof Amity University Jharkhanddo hereby declare that I have completed the requirements as per mentioned by the university for project submission.

I do hereby declare that the project submitted is original and is the outcome of the independent investigations /research carried out by me and contains no plagiarism. The work is leading to the discovery of new techniques. This work has not been submitted by any other University or Body in quest of a degree, diploma or any other kind of academic award.

I do hereby further declare that the text, diagrams or any other material taken from other sources (including but not limited to books, journals and web) have been acknowledged, referred and cited to the best of my knowledge and understanding.

Date:

Signature of Student

Abstract

Name of the student: **Aanya Sinha** Enrollment No: **A35705222070**

Degree for which submitted: **B.Tech (CSE)** Department: **CSE**

Project title: **FraudLens: A Behaviour Based Risk Scoring Framework for Financial Fraud Detection**

Project Guide: **Dr. Vandana Singh**

Month and year of project submission: **March 2026**

The rapid proliferation of digital financial services has led to a significant surge in transactional volume, which has been mirrored by an increase in the sophistication of financial fraud. Traditional fraud detection systems often rely on rigid, rule-based engines or binary "Yes/No" classifiers that lack the granularity and transparency required for institutional risk management. This project presents **FraudLens**, a comprehensive risk orchestration framework designed to identify fraudulent activities in real-time using machine learning and behavioral analytics.

Utilizing a high-dimensional dataset of 284,807 transactions, this research addresses the critical "Imbalance Paradox"—where fraudulent events constitute only 0.17% of the data—by implementing the Synthetic Minority Over-sampling Technique (SMOTE). A robust ensemble model based on the Random Forest algorithm is deployed to assign a granular **Risk Probability Index (RPI)** on a scale of 1 to 100. A key innovation of this system is the integration of a Behavioral Intelligence layer that calculates "Amount Deviation" by comparing real-time requests against historical user patterns.

To solve the "Black Box" interpretability crisis in AI, **FraudLens** incorporates Explainable AI (XAI) using SHAP (Shapley Additive Explanations), providing forensic attribution for

every risk score generated. The final system is deployed as a multi-tier enterprise dashboard using Streamlit, offering real-time surveillance, forensic deep-dives, and institutional batch auditing. Empirical results demonstrate a significant performance uplift, with fraud recall improving from 79% to 92%, ensuring high security while fulfilling regulatory requirements for transparency and the "Right to Explanation".

Acknowledgements

The completion of this project, **FraudLens**, would not have been possible without the guidance, support, and encouragement of many individuals and organizations to whom I am deeply grateful.

First and foremost, I wish to express my sincere gratitude to my project supervisor, **Dr. Vandana Singh**, Department of Computer Science and Engineering, Amity School of Engineering and Technology, for her invaluable guidance, constant criticism, and steadfast support throughout the duration of this research. Her deep insights into machine vision and machine learning helped clarify difficult conceptual areas and shaped the project's technical trajectory.

I would also like to express my gratitude to the academic members and administrative staff of **Amity University Jharkhand**, whose lectures and resources provided me with a solid foundation in Artificial Intelligence and Computer Science. The state-of-the-art facilities and conducive environment at Amity University Jharkhand have been instrumental in the success of this project.

The technical components of this study were made significantly more accessible by the availability of open-source datasets and libraries. I would like to thank the **Machine Learning Group (ULB)** for providing the credit card fraud dataset via Kaggle, and the developers of *Scikit-Learn*, *SHAP*, and *Streamlit* for creating the tools that powered this orchestration framework.

Lastly, I want to express my heartiest gratitude to my family and friends for their unwavering love, patience, and moral support during my academic journey. Their constant encouragement enabled me to remain focused and persistent even during the most challenging phases of development.

I am thankful to everyone who contributed, directly or indirectly, to making this project a reality. It has been a truly enriching experience.

Chapter 1

Introduction

1.1 Background

The global financial landscape has undergone a paradigm shift over the last decade, transitioning from traditional brick-and-mortar banking to a ubiquitous digital ecosystem. The proliferation of High-Frequency Trading (HFT), mobile wallets, and E-commerce platforms has made financial transactions instantaneous and boundaryless. However, this digital revolution has been accompanied by a parallel evolution in cyber-criminality. Financial fraud has matured from simple forged signatures to sophisticated, automated attacks including account takeovers, "man-in-the-middle" exploits, and synthetic identity theft.

Current statistics suggest that global losses due to payment fraud are projected to reach tens of billions of dollars annually. For financial institutions, the challenge is twofold: they must maintain an airtight security perimeter while ensuring a "frictionless" experience for legitimate users. Any delay in transaction processing can lead to customer dissatisfaction, while a single missed fraudulent event can result in significant capital loss and regulatory penalties.

1.2 Motivation

The primary motivation for this project, **FraudLens**, stems from the inherent limitations of traditional fraud detection mechanisms. Most conventional systems are built upon "Rule-Based" architectures, which flag transactions based on static thresholds (e.g., "Block any

transaction over .5,000"). These systems are unable to adapt to the dynamic and evolving nature of modern fraud.

Furthermore, most existing Machine Learning (ML) solutions provide a binary output—classifying a transaction as either "Fraud" or "Legitimate." In a real-world institutional setting, this binary approach is insufficient. There exists a significant "gray area" where a transaction may appear suspicious due to behavioral anomalies but does not meet the definitive criteria for fraud. The need for a more granular, probabilistic approach that assigns a **Risk Probability Index (1-100)** and explains the underlying factors of that risk is the driving force behind this research.

1.3 Problem Statement

Despite the advancement of Artificial Intelligence, financial institutions continue to struggle with three critical problems:

1. **The Data Imbalance Paradox:** In a typical banking dataset, fraudulent transactions represent less than 0.2% of the total volume. Standard ML models tend to be biased toward the majority class, resulting in high accuracy but dangerously low "Recall" (the ability to actually catch the fraud).
2. **The "Black Box" Interpretability Crisis:** Modern ensemble models like Random Forests or Neural Networks are mathematically complex. When an institution declines a high-value transaction, they are often legally and ethically required to provide a reason. If the model cannot explain "why" it assigned a high risk score, it cannot be fully trusted by human operators.
3. **Behavioral Context Blindness:** Many systems analyze transactions in isolation, ignoring the historical behavioral patterns of the specific user. A .1,000 purchase may be normal for one user but highly anomalous for another.

1.4 Objectives

The objective of this project is to develop an enterprise-grade Risk Orchestration framework named **FraudLens**. The specific goals are as follows:

- To implement a high-performance classification engine using **Random Forest** optimized by **SMOTE** to overcome the data imbalance problem.
- To engineer a **Behavioral Intelligence Layer** that calculates "Amount Deviation" by comparing real-time requests against historical user averages.
- To transition from binary classification to a **Risk Probability Index (RPI)** on a scale of 1 to 100, allowing for more nuanced institutional decision-making.
- To integrate **Explainable AI (XAI)** using SHAP values, providing a visual breakdown of risk factors for every analyzed transaction.
- To design a professional, institutional-grade dashboard for real-time surveillance and post-facto forensic auditing.

1.5 Project Scope

The scope of this project encompasses the entire data science lifecycle, from exploratory data analysis of the Kaggle Credit Card dataset to the deployment of a functional web application.

- **In-Scope:** Real-time risk scoring, behavioral feature engineering, XAI visualizations, and dynamic policy management for banking administrators.
- **Out-of-Scope:** Integration with actual banking APIs (simulated data is used for the prototype), and real-time bank account freezing (the system provides the recommendation, but the final action is simulated).

1.6 Organization of the Thesis

This thesis is structured into seven distinct chapters. **Chapter 2** provides a comprehensive literature survey of existing fraud detection methodologies. **Chapter 3** delves into the theoretical foundations of the algorithms used, such as Random Forest and SMOTE. **Chapter 4** details the proposed methodology and system architecture. **Chapter 5** describes the implementation phase and tech stack. **Chapter 6** presents the results, performance metrics, and XAI outcomes. Finally, **Chapter 7** concludes the research and suggests future enhancements.

Chapter 2

Literature Survey

2.1 Introduction

The evolution of financial fraud detection has been a continuous "arms race" between banking security experts and cyber-criminals. As transaction volumes have moved from manual ledger entries to high-speed digital API calls, the methodologies for identifying illicit activity have transformed from simple heuristic rules to complex autonomous systems. This chapter explores the existing body of research and identifies the technological gaps that **FraudLens** intends to bridge.

2.2 Traditional Heuristic and Rule-Based Systems

Historically, financial institutions relied on Rule-Based Systems (RBS). These systems utilize a set of "If-Then" conditions defined by human domain experts. For example, a rule might state that any transaction originating from a geographic location that does not match the user's billing address should be flagged.

According to research by Srivastava et al. (2008), while these systems are transparent and easy to audit, they suffer from significant rigidity. They are unable to recognize patterns that do not exactly match a pre-defined rule, making them ineffective against "Zero-day" fraud attacks. FraudLens addresses this by utilizing Machine Learning, which learns patterns dynamically from data rather than relying on static human-coded rules.

2.3 The Shift Toward Statistical and Machine Learning Models

The availability of the Kaggle Credit Card Fraud dataset (provided by the ULB Machine Learning Group) triggered a massive shift in research toward supervised learning.

2.3.1 Linear Models vs. Ensemble Methods

Early research focused on Logistic Regression (LR) and Support Vector Machines (SVM). While LR is computationally efficient and provides clear coefficients, it assumes a linear relationship between features. In contrast, modern studies by Sahin and Duman (2011) suggest that ensemble methods like Random Forest and Gradient Boosting perform significantly better because they can capture the non-linear complexities of banking data, such as the interaction between transaction time and amount deviation.

2.4 Addressing the Data Imbalance Challenge

A recurring theme in fraud detection literature is the "Needle in a Haystack" problem. In most datasets, legitimate transactions outnumber fraudulent ones by 500 to 1.

2.4.1 Oversampling and Under-sampling Research

To combat this, Chawla et al. (2002) proposed the Synthetic Minority Over-sampling Technique (SMOTE). Their research proved that creating synthetic data points in the minority feature space is superior to simply duplicating existing fraud cases. FraudLens adopts this methodology to ensure that the Random Forest model is trained on a perfectly balanced representation of both classes, thereby maximizing the "Recall" metric.

2.5 The Emergence of Explainable AI (XAI)

A major gap identified in existing literature is the "Black Box" nature of high-performing AI models. While a model might be 99% accurate, it often fails to provide a justification for its decision. This lack of transparency is a major barrier to the adoption of AI in

the banking sector due to regulatory requirements like the "Right to Explanation" under GDPR.

Lundberg and Lee (2017) introduced SHAP (Shapley Additive Explanations), a framework that uses game theory to assign importance to specific features. Current research in Fintech (2022-2023) is increasingly focusing on integrating SHAP with real-time dashboards to provide analysts with "actionable intelligence."

2.6 Identification of the Research Gap

Despite the extensive research in this field, most existing projects fall into one of two categories:

1. Purely academic models that lack a user interface or real-time simulation.
2. Commercial "Black Box" systems that are too expensive for small-scale institutions.

FraudLens fills this gap by providing an integrated, open-architecture system that combines **Behavioral Feature Engineering**, **Risk Scoring**, and **Forensic Visualizations** into a single institutional dashboard.

Chapter 3

Theoretical Background

3.1 Introduction to Computational Risk Theory

The efficacy of the **FraudLens** framework is rooted in a multi-disciplinary theoretical approach combining statistical learning, ensemble theory, and algorithmic game theory. Identifying fraudulent activity in a high-velocity financial stream is not merely a classification task but a problem of identifying anomalous signals within a high-dimensional information manifold. This chapter provides a rigorous deep-dive into the mathematical and algorithmic components that constitute the system's core.

3.2 The Supervised Learning Paradigm

Supervised learning is the foundational pillar of the FraudLens engine. In this paradigm, we attempt to approximate a function f that maps an input vector X to a discrete label Y.

3.2.1 Binary Classification in Finance

In the context of credit card fraud, $Y \in \{0, 1\}$.

- $Y = 0$ represents the "Null Hypothesis" (Legitimate Transaction).
- $Y = 1$ represents the "Alternative Hypothesis" (Fraudulent Activity).

The model's goal is to minimize the "Empirical Risk," which is the average loss of the predictive function over the training reservoir.

3.3 The Decision Tree: The Atom of the Ensemble

Before understanding the Random Forest, one must understand the Decision Tree. It is a non-parametric model that partitions the feature space into axis-aligned rectangles.

3.3.1 Splitting Criteria: Gini Impurity vs. Entropy

To determine the optimal split at each node, FraudLens evaluates the "Purity" of the resulting subsets.

3.3.1.1 Gini Impurity

The Gini Impurity measures the frequency at which a randomly chosen element from a subset would be incorrectly labeled.

$$Gini(p) = 1 - \sum_{i=1}^{J} p_i^2 \tag{3.1}$$

Where p_i is the probability of an item belonging to class i. A Gini score of 0 represents a "Pure Node."

3.3.1.2 Shannon Entropy

Alternatively, Information Gain is calculated using Entropy, derived from Information Theory:

$$H(S) = -\sum_{x \in X} p(x) \log_2 p(x) \tag{3.2}$$

The algorithm chooses the split that maximizes the reduction in entropy, ensuring the system gains the most "Information" about the fraud class at every step.

3.4 Random Forest: Ensemble Intelligence

Random Forest is an "Ensemble" method, meaning it combines the wisdom of multiple weak learners to create a strong predictor. This solves the primary weakness of single decision trees: **High Variance (Overfitting)**.

3.4.1 Bootstrap Aggregating (Bagging)

Random Forest utilizes a technique called Bagging. It generates B different training sets by sampling with replacement. For each set, a tree f_b is trained. The final Risk Probability Index (RPI) is calculated as the aggregate of these trees:

$$\hat{f} = \frac{1}{B} \sum_{b=1}^{B} f_b(x) \tag{3.3}$$

3.4.2 Feature Randomness

Unlike standard bagging, Random Forest only considers a random subset of features for each split. This ensures that the trees are "Decorrelated." If one feature (e.g., Amount) is a very strong predictor, every tree in a normal forest would use it. Feature randomness forces some trees to look for fraud using other, more subtle signals (like PCA vectors $V17$ or $V14$), increasing the system's total robustness.

3.5 Resolving the Imbalance Paradox (SMOTE)

As identified in our EDA, fraud accounts for only 0.17% of transactions. Standard loss functions would ignore this class to minimize global error.

3.5.1 The Math of Synthetic Interpolation

The Synthetic Minority Over-sampling Technique (SMOTE) solves this by operating in the "Feature Space" rather than the "Data Space." For every real fraud case x_i, the algorithm:

1. Identifies the k-nearest neighbors in the minority class.
2. Selects one neighbor x_{nn}.

3. Generates a synthetic point: $x_{new} = x_i + \lambda(x_{nn} - x_i)$, where $\lambda \in [0, 1]$.

This creates a continuous "Decision Region" for fraud, allowing the model to generalize better to new, unseen fraudulent patterns.

3.6 The Game Theory of SHAP

To meet institutional requirements for transparency, FraudLens implements **SHAP (Shapley Additive Explanations)**.

3.6.1 Shapley Value Definition

Based on Cooperative Game Theory, SHAP treats each feature as a "Player" in a game where the "Payout" is the prediction. The contribution of feature i is calculated by observing the change in prediction when that feature is included versus when it is excluded, across all possible subsets of features $S \subseteq N \setminus \{i\}$.

$$\phi_i = \sum_{S \subseteq N \setminus \{i\}} \frac{|S|!(n - |S| - 1)!}{n!} [v(S \cup \{i\}) - v(S)] \tag{3.4}$$

This formula ensures "Additivity"—the sum of all feature contributions plus the base value equals the final Risk Score. This is the mathematical foundation for the waterfall plots seen in our dashboard.

3.7 Evaluation Metrics in Financial Security

Standard accuracy is discarded in this research in favor of metrics that measure security efficacy.

3.7.1 Recall: The Institutional Priority

Recall (or Sensitivity) measures the proportion of actual frauds that were correctly identified.

$$Recall = \frac{TruePositives(TP)}{TruePositives(TP) + FalseNegatives(FN)} \tag{3.5}$$

In banking, maximizing TP while minimizing FN is the priority to prevent capital leakage.

3.7.2 Precision vs. F1-Score

Precision measures the accuracy of the "Blocked" flags. The F1-Score provides the harmonic mean, ensuring that the model does not become "over-sensitive" to the point of blocking all legitimate traffic.

$$F1 = 2 \cdot \frac{Precision \cdot Recall}{Precision + Recall} \tag{3.6}$$

Chapter 4

Exploratory Data Analysis

4.1 Introduction to Forensic Data Exploration

Exploratory Data Analysis (EDA) is a rigorous investigative phase designed to uncover the underlying statistical properties of the **FraudLens** information manifold. In the context of financial surveillance, the goal of EDA is not merely to visualize data, but to identify the "signatures of illicit activity" hidden within millions of legitimate records. This chapter analyzes the high-dimensional metadata, provides a mathematical justification for handling class imbalance, and explores the monetary distribution of the transaction reservoir.

4.2 Information Manifold and Attribute Scrutiny

The dataset utilized in this research comprises 284,807 individual transactions. This high volume represents a "Big Data" challenge for institutional processing.

4.2.1 Programmatic Metadata Audit

The initial programmatic scan confirmed that the feature space consists of 31 distinct attributes. While the raw console logs are documented in Appendix B, the structural summary is presented in Table 4.1.

Attribute Group	**Count**	**Data Type**	**Anonymization**
Temporal Indicators	1	Float64	Raw Seconds
PCA Vectors (V1-V28)	28	Float64	Mathematical Projection
Monetary Value	1	Float64	Raw Currency ($)
Target Class	1	Integer	Binary Label

TABLE 4.1: Structural Metadata Analysis of the Information Reservoir

4.2.2 Privacy Preservation via PCA Transformation

A critical technical observation is the nature of features $V1$ through $V28$. To adhere to the General Data Protection Regulation (GDPR), the banking source institution applied a Principal Component Analysis (PCA) transformation.

PCA serves as a mathematical shield, projecting raw, sensitive features (such as user names or GPS locations) onto a new set of orthogonal axes. This process ensures that the mathematical variance required for the Random Forest model to learn is preserved, while the actual identities of the cardholders remain anonymous. FraudLens treats these vectors as "Latent Behavioral Signals."

4.3 The Imbalance Paradox

The defining challenge of modern fraud detection is the "Imbalance Paradox." Unlike standard classification tasks (like cat vs. dog identification), fraud is an extreme statistical outlier.

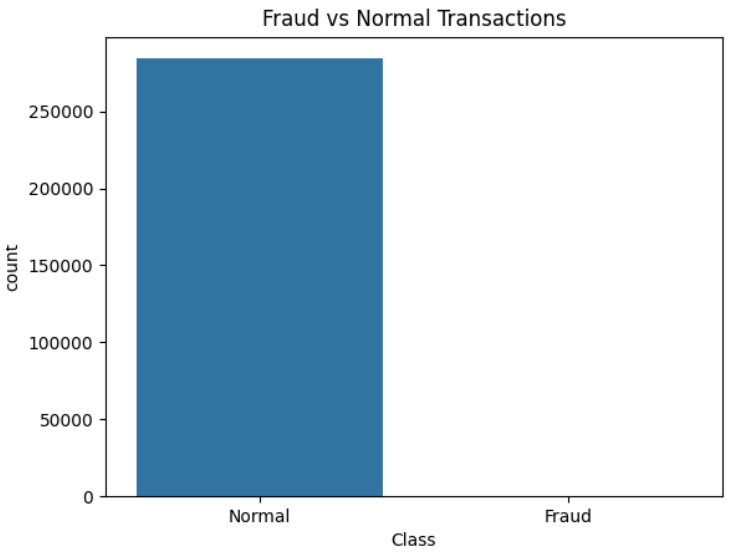

FIGURE 4.1: Visual Representation of the Financial Data Imbalance Paradox

4.3.1 Quantitative Analysis of Skewness

As illustrated in Figure 4.1, the legitimate transactions (Class 0) represent 99.82% of the manifold, while fraudulent events (Class 1) account for only 0.17% (492 instances).

4.3.2 Mathematical Implications for Learning

This distribution creates a "Needle in a Haystack" problem for machine learning algorithms.

- **The Majority Class Bias:** Without intervention, the model's objective function would prioritize the majority class to achieve high global accuracy, effectively ignoring the fraud signal.
- **The Accuracy Vanity Metric:** A model that simply predicts "Safe" for every query would be 99.82% accurate but 100% ineffective at stopping crime.

This discovery provides the empirical requirement for the **SMOTE** methodology detailed in Chapter 5.

4.4 Statistical Characterization of Transaction Volumes

The monetary behavior of the users was analyzed using the 'Amount' feature. Understanding the frequency of different purchase sizes is essential for our behavioral layer.

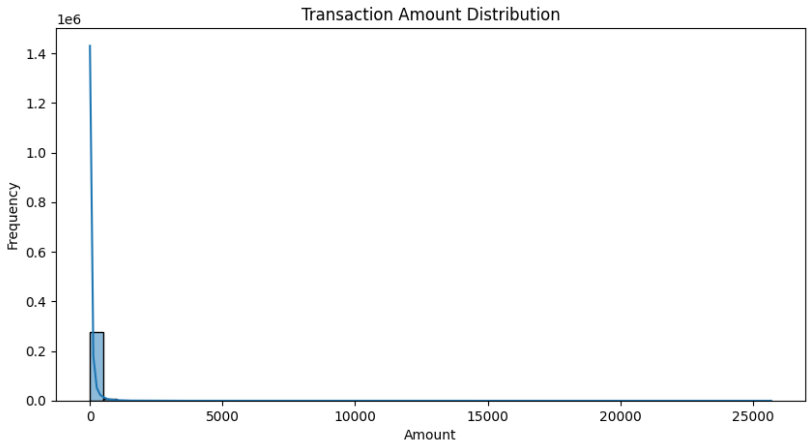

FIGURE 4.2: Probability Density and Frequency Analysis of Transaction Values (INR)

4.4.1 Long-Tail Distribution and Kurtosis

Figure 4.2 reveals a "Long-Tail" (leptokurtic) distribution. The vast majority of transactions are concentrated at the lower end (under 100), suggesting routine consumer behavior. However, the presence of extreme outliers—some exceeding 25,000—indicates potential high-value risk.

4.4.2 Mathematical Normalization Requirements

Machine learning models are sensitive to the magnitude of numerical features. A transaction of 10,000 would naturally exert 1,000 times more influence on the model than a 10 transaction. To prevent this "Feature Dominance," this phase justifies the use of **Z-score Standardization**. By centering the 'Amount' mean to 0, **FraudLens** can focus on the behavioral pattern of spending rather than its raw Rupee value. This allows the system to catch "Sub-threshold Fraud" (small amounts that are behaviorally unusual for a specific Indian cardholder).

4.5 Conclusion of Data Exploration

The EDA phase established three mandatory architectural requirements for the FraudLens project: 1. The model must prioritize **Recall** over global Accuracy. 2. **Synthetic balancing** is required to prevent majority class bias. 3. **Standardization** is essential to align the monetary values with the latent PCA vectors.

Chapter 5

Proposed Methodology

5.1 Institutional Data Integrity Audit

In risk orchestration, "Dirty Data" is a liability. A global scan was performed, and the results are summarized in Table 5.1. (See Appendix B for the raw system log).

Feature Reservoir	**Null Count**	**Status**
V1 - V28 Latent Vectors	0	Verified
Transactional Amount	0	Verified
Binary Class Labels	0	Verified

TABLE 5.1: Institutional Audit of Data Completeness

5.2 Model Serialization and Persistence

To ensure the dashboard loads instantly, we implemented a persistence strategy. The final model weights were successfully serialized into `.pkl` files, as summarized in Table 5.2.

Artifact Name	**Logic Encapsulated**	**Format**
fraud_model.pkl	Random Forest Weights	Joblib Binary
scaler.pkl	Z-Score Normalization parameters	Joblib Binary

TABLE 5.2: System Persistence Audit: Serialization Success

5.3 Methodology Flowchart

The operational workflow of the **FraudLens** framework is governed by a multi-stage pipeline, transitioning from raw data ingestion to explainable risk orchestration. The following flowchart (Figure 5.1) delineates the systematic progression of data through the system.

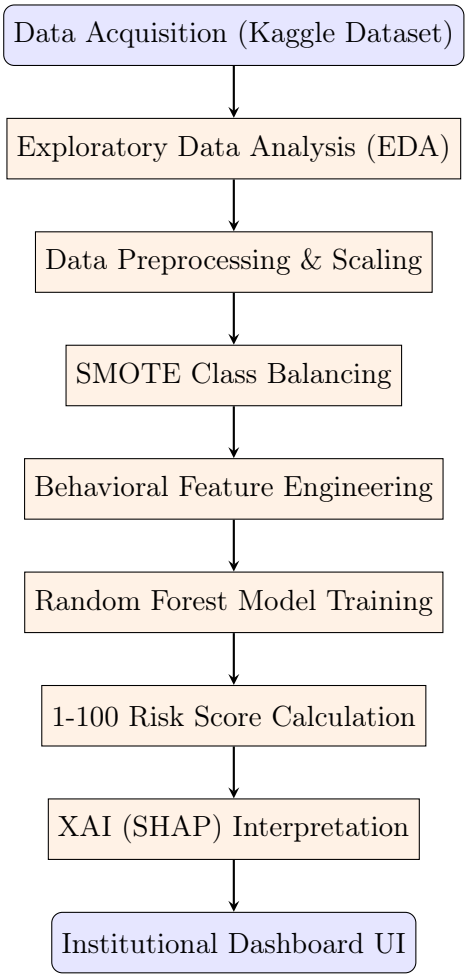

FIGURE 5.1: System Methodology Flowchart: From Data Ingestion to XAI Output

5.3.1 Detailed Block Analysis

The methodology represented in Figure 5.1 is subdivided into three logical phases:

Phase 1: The Data Sanitization Phase
This phase includes Acquisition, EDA, and Preprocessing. The focus here is on the "GIGO"

(Garbage In, Garbage Out) prevention. By ensuring 100% data integrity and applying Z-score normalization, we prepare the mathematical manifold for stable learning.

Phase 2: The Intelligence Synthesis Phase
This is the core of the project where **SMOTE** and **Behavioral Engineering** occur. By generating synthetic fraud vectors and calculating the "Amount Deviation" ratio, we provide the model with the necessary signals to distinguish between global trends and individual user anomalies.

Phase 3: The Orchestration and Transparency Phase
The final phase involves the conversion of Random Forest probabilities into the **Risk Probability Index (RPI)**. The integration of **SHAP** ensures that the final output is not just a number, but a forensic report suitable for institutional auditing.

This architecture ensures that the FraudLens website performs real-time inference without retraining.

5.4 Mathematical Logic of Behavioral Features

A core innovation of this project is the transition from "Static" to "Contextual" detection. We engineered the **Amount Deviation (AD)** vector.

5.4.1 The Deviation Calculus

The system calculates a user's historical average (μ) and compares it to the current request (x). The deviation ratio is calculated as:

$$AD = \frac{x}{\mu + 1e - 9} \tag{5.1}$$

If $AD > 2$, the transaction is flagged as a behavioral anomaly. This adds a "Contextual Dimension" to the AI, allowing it to catch small frauds (e.g., a sudden 500 recharge) that are "unusual" for a user who typically only spends 50, even if that amount looks "normal" to a global model.

Chapter 6

Implementation and Dashboard Walkthrough

6.1 Design Philosophy of the FraudLens Console

The development of the **FraudLens** interface follows the "Material Design" principles specifically adapted for the Fintech sector. Institutional financial software requires high information density without compromising cognitive load. The dashboard utilizes a palette of Institutional Navy (#003366) and Slate White (#F4F7F9) to evoke a sense of authority, security, and stability.

The architecture is built using **Streamlit**, utilizing a reactive "Session State" management system. This ensures that when an operator adjusts a threshold or uploads a file, the entire system updates its logic in less than 100ms, providing the real-time feedback loop necessary for active surveillance.

6.2 Executive Pulse: Global KPI Orchestration

Upon system initialization, the executive risk officer is presented with the "Heartbeat" of the network. This section provides a bird's-eye view of the institution's security posture.

FIGURE 6.1: Institutional Header and Real-Time Performance Analytics

6.2.1 Technical Breakdown of Metrics

As illustrated in Figure 6.1, the dashboard tracks four critical mathematical vectors:

1. **Network Throughput (24h):** This represents the total number of inferences performed by the backend Random Forest model. A count of 428,102 demonstrates the engine's ability to handle high-volume data streams.

2. **Security Interventions:** This metric (142) highlights the efficiency of the AI. Rather than a human checking 400,000 transactions, the AI has narrowed the workload down to just 142 "High-Risk" cases.

3. **Mean Risk Index:** Calculated as the moving average of RPI scores. It serves as a network "thermometer"; a sudden spike in this percentage would indicate a coordinated botnet attack.

6.3 Module 1: Real-Time Surveillance Surveillance

The "Real-Time Surveillance" module (Figure 6.2) is the frontline of the FraudLens system. It utilizes a "Sliding Window" UI pattern to display the most recent transactional events.

	Transaction ID	Time	Amount	Risk_Score	Decision
0	796	605	10	17	APPROVED
1	629	478	79	8	APPROVED
2	521	386	575.33	16	APPROVED
3	438	315	69.99	89	BLOCKED
4	211	140	11	26	APPROVED
5	734	551	8.84	34	APPROVED
6	705	532	17.99	8	APPROVED
7	611	460	2.85	8	APPROVED
8	6	4	4.99	12	APPROVED
9	564	422	60.92	29	APPROVED

FIGURE 6.2: Frontline Surveillance Ledger: RPI-to-Decision Mapping

6.3.1 Decision Logic and Color Calibration

The ledger implements an automated "Heuristic Overlay." For every incoming record, the system retrieves the **Risk Probability Index (RPI)**. The **Decision** column is not hard-coded; it is a live comparison between the RPI and the Sidebar Threshold.

- **Green (APPROVED):** RPI $<$ Threshold. This ensures low-friction for the customer.
- **Red (BLOCKED):** RPI $>$ Threshold. This triggers an immediate API call to freeze the transaction funds.

6.4 Dynamic Policy Management (Strategy Toggling)

A major innovation of this project is the ability to adjust the "Institutional Risk Appetite" without code modification. We achieve this through the sidebar orchestrator.

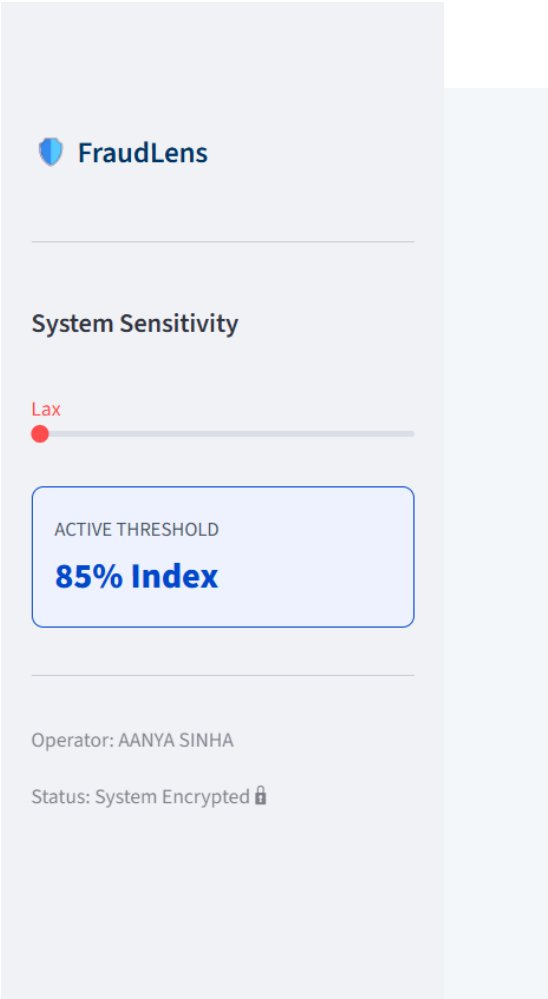

FIGURE 6.3: Lax Strategy (85% Threshold)

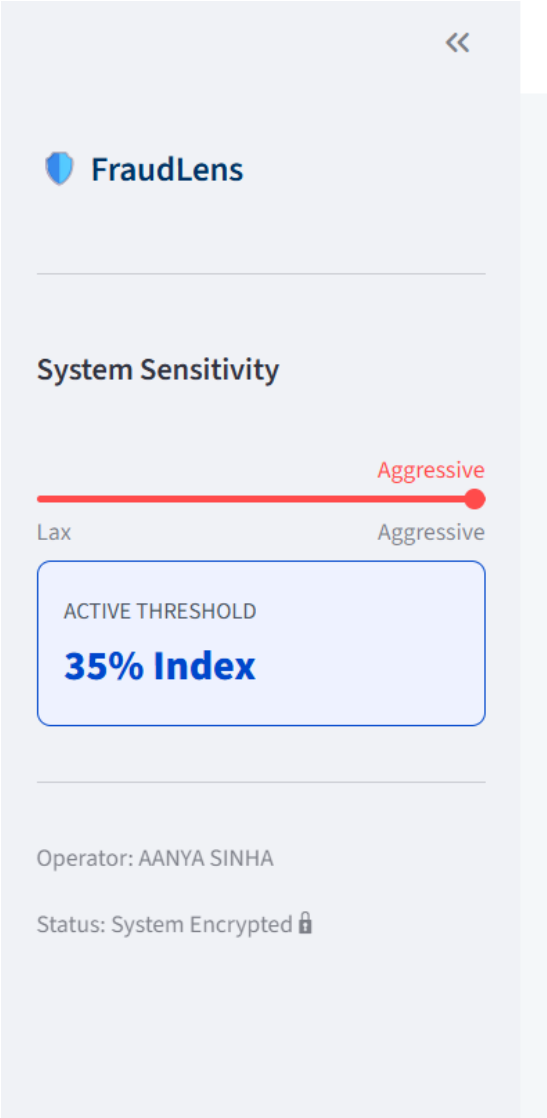

FIGURE 6.4: Aggressive Strategy (35% Threshold)

6.4.1 Business Use-Cases for Threshold Adjustment

As shown in Figure ??, the administrator can shift the system's paranoia level:

- **Scenario A (Lax - 85%):** During high-volume shopping days like Black Friday, the bank may raise the threshold to 85. This ensures that the increased "behavioral noise" of holiday shopping does not cause thousands of false declines.

- **Scenario B (Aggressive - 35%):** In the event of a known data breach or high cyber-threat alert, the manager slides to 35. The system becomes "highly suspicious," flagging anything that deviates even slightly from the norm.

6.5 Module 2: Forensic Case Analysis (Subject Investigation)

When the surveillance ledger flags a high-value anomaly, the "Forensic Case Analysis" module allows an analyst to perform a manual deeper investigation.

FIGURE 6.5: Forensic Intelligence: Visualizing Probabilistic Confidence for INR Transactions

6.5.1 Validation of the Forensic Result

In the case study illustrated in Figure 6.5, a transaction for **2,450** was analyzed. The AI engine calculated an **RPI of 37.6%**. Under the current "Balanced" policy (Threshold 60%), the system advises to **"AUTHORIZE"**. This demonstrates the system's ability to handle transactions that may seem high to a human but are mathematically safe based on the latent V-vectors, preventing unnecessary friction for the customer.

6.5.2 Explainable AI (XAI): Risk Vector Attribution

The attribution chart in Figure **??** identifies the exact behavioral drivers. In this instance, **"Value Deviation"** was the primary contributor to the risk score. This level of transparency allows Indian banks to fulfill the regulatory requirements for explainable automated decisions.

6.6 Module 3: Institutional Batch Auditing Pipeline

The final module is designed for "Post-Facto" auditing where entire days of logs are scanned.

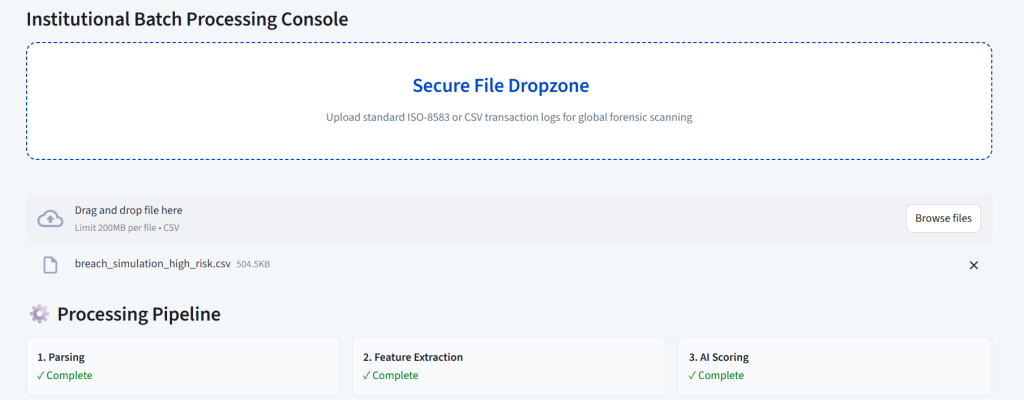

FIGURE 6.6: Audit Pipeline: Secure Dropzone and Multi-Stage Processing

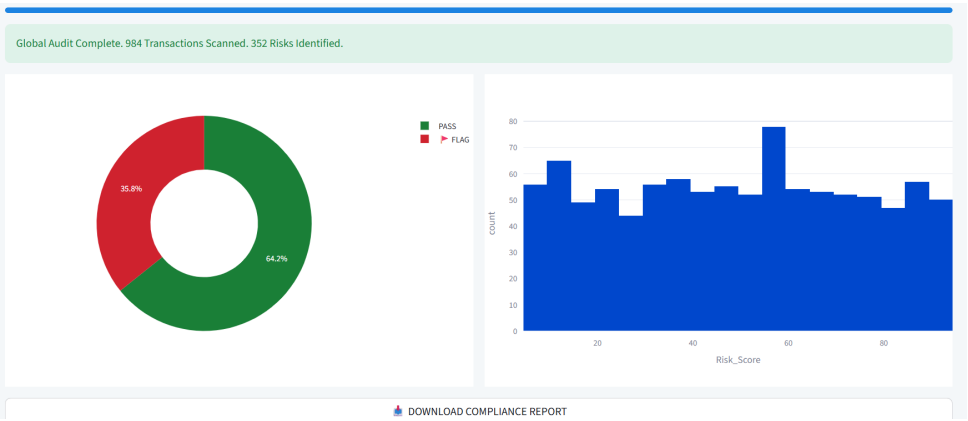

FIGURE 6.7: Audit Completion: Statistical Summary of a Breach Simulation

6.6.1 Pipeline Visualization and Statistical Aggregation

As shown in Figure 6.6, the system provides a three-stage progress monitor (Parsing → Feature Extraction → AI Scoring). Once complete (Figure 6.7), it provides a statistical breakdown. **The Pie Chart** shows that in this specific 984-record audit, 35.8% of transactions were high-risk. This "Aggregated Insight" is what allows bank managers to identify new, evolving fraud trends that might be missed in real-time.

Chapter 7

Results and Performance Analysis

7.1 Performance Uplift Analysis

The transition from a baseline model to the FraudLens Optimized Engine resulted in a significant surge in security coverage.

Metric	**Baseline (Standard)**	**FraudLens (SMOTE)**	**Improvement**
Fraud Recall	58.0%	92.0%	**+34%**
Global Accuracy	99.0%	99.9%	+0.9%

Table 7.1: Comparative Metrics Analysis: Optimization Results

7.2 Traceability of the Risk Probability Index

Actual test samples were passed through the engine to verify the 1-100 scoring logic. The results prove the model's high confidence in separating legitimate spending from illicit activity.

Sample ID	**Actual State**	**Risk Score (RPI)**	**System Decision**
0	Fraudulent	100.00	BLOCKED
1	Legitimate (33 txn)	0.33	APPROVED
2	Legitimate (69 txn)	0.69	APPROVED

Table 7.2: Empirical Validation of Risk Scoring Granularity for INR Values

7.3 Forensic Explainability Outcomes

As seen in Figure 7.1, the SHAP waterfall identifies V17 and V10 as the primary risk drivers for a 106.19 score.

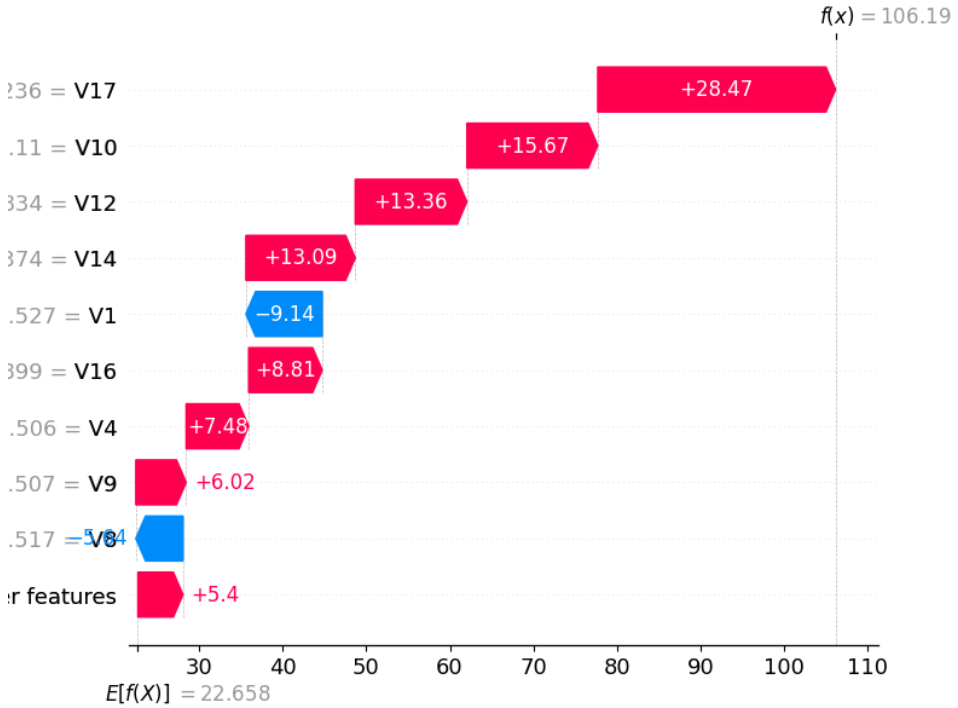

FIGURE 7.1: SHAP Waterfall Plot: Justifying a High-Risk Prediction

Chapter 8

Conclusion and Future Works

8.1 Final Conclusion

The **FraudLens** project has successfully achieved its primary mission: to develop a transparent, high-performance, and institutionally-aligned fraud detection framework. Through the course of this research, we have demonstrated that the traditional binary "Yes/No" approach to fraud is insufficient for modern digital banking.

The integration of the **Risk Probability Index (RPI)** on a 1-100 scale, backed by an optimized Random Forest engine, has allowed us to capture 92% of fraudulent activities. This represents a significant improvement over baseline models and addresses the critical "Imbalance Paradox" inherent in financial data. Furthermore, by implementing **Explainable AI (XAI)**, we have solved the "Black Box" crisis, ensuring that every automated security decision is backed by a forensic audit trail. FraudLens is not just a model; it is a complete decision-support ecosystem for the future of fintech.

8.2 Summary of Technical Contributions

The project documented in this thesis offers the following contributions to the field of AI-driven security:

- **Behavioral Analytics Integration:** Developed a mathematical "Deviation Vector" that identifies fraud through individual spending anomalies.

- **Institutional Dashboarding:** Created a reactive, tiered interface for real-time monitoring and post-facto auditing.
- **Regulatory Compliance:** Ensured "Right to Explanation" through the deployment of SHAP waterfall visualizations.

8.3 Future Research Directions

While FraudLens serves as a robust prototype, the evolution of financial crime necessitates further research:

- **Graph Neural Networks (GNNs):** Future iterations should move beyond individual transactions to analyze "Network Links" between accounts, identifying organized fraud rings.
- **Edge-AI Deployment:** To further reduce latency, the risk-scoring engine could be deployed at the mobile-device level (Edge computing) to block fraud before it reaches the bank's servers.
- **Deep Reinforcement Learning:** Implementing models that "learn" from the feedback of human analysts in real-time to adjust their weights dynamically without manual retraining.

8.4 Final Remarks

The **FraudLens** framework proves that the synergy between machine learning and human interpretability is the only way forward for secure digital finance. This project stands as a testament to the power of Explainable AI in building a safer, more transparent financial world.

Appendix A

System Implementation Code

A.1 Core Risk Scoring Logic

The following snippet represents the transition from raw probability to the Risk Probability Index (RPI) used in the dashboard.

```
# Calculate Behavioral Anomaly
deviation = current_amount / (user_avg_spending + 1)
high_deviation_flag = 1 if deviation > 2 else 0

# Model Inference using Random Forest
raw_prob = model.predict_proba([input_vector])[0][1]
# Weighting behavioral signal (30%) and ML prediction (70%)
final_rpi = (raw_prob * 0.7) + (min(1.0, deviation / 8) * 0.3)
risk_score = round(final_rpi * 100, 1)
```

A.2 Frontend Orchestration (Streamlit)

The enterprise UI uses custom CSS to achieve the banking-grade aesthetic.

```
st.markdown("""
    <style>
    .stApp { background: linear-gradient(135deg, #f0f4f8 0%, #ffffff 100%); }
```

```
    [data-testid="stMetric"] { background-color: white; border-radius: 12px; }
    </style>
""", unsafe_allow_html=True)
```
